

## Business Modeling Process

As shown in the above diagram I have Four lanes representing my main four actors in the system of Crop Disease Early Detection.

The Crop Disease Early Detection System allows farmers to report crop abnormalities and obtain automated disease analysis. The process begins when a farmer notices unusual symptoms on a crop and sends a report that includes the crop type, symptoms, severity, and location. The system validates the submitted report to ensure that all needed information is present.

Once the report has been validated, the system examines the symptoms using previously saved disease data. A matching algorithm analyzes submitted symptoms to known disease symptom descriptions to determine the most likely condition and generate a confidence score. The machine then determines a risk rating based on severity and matching confidence.

Following analysis, the system automatically generates relevant recommendations. The technology also tracks the frequency of diseases discovered in each place. If five or more instances of the same disease are reported in the same district within seven days, an outbreak warning is generated and submitted to the District Agriculture Officer.

Officers utilize this data to develop intervention methods. In addition, academics and farm officers can analyze trends, hotspots, and risk patterns using dashboards.
